A combined cycle power plant is an assembly of heat engines that work in tandem from the same source of heat, converting it into mechanical energy. On land, when used to make electricity the most common type is called a combined cycle gas turbine plant. The same principle is also used for marine propulsion, where it is called a combined gas and steam plant. Combining two or more thermodynamic cycles improves overall efficiency, which reduces fuel costs. The principle is that after completing its

This technology uses both gas and steam turbine together to produce up to 50% more electricity than a traditional turbine. CCGT uses gas turbines to drive an electrical generators and recovers waste heat from the turbine exhaust to generate steam. A CCGT has high thermal efficiency - up to 60% or more - compared with the 40% from a single cycle gas turbine. It achieves this by recovering waste heat from the gas turbine exhaust to fire a boiler (heat-recovery steam generator - HRSG) that in turn powers a steam turbine generator (STG). Unfortunately, most CCGTs were built as a baseload plant.

Additional energy can be usefully extracted by using the hot exhaust gases to raise steam and produce further electricity conventionally in a turbine/alternator. This combination is described as a Combined Cycle Gas Turbine (CCGT).

Inner Workings of a Combined-Cycle Power Plant. A combined-cycle power plant uses both a gas and a steam turbine together to produce up to 50 percent more electricity from the same fuel than a traditional simple-cycle plant. The waste heat from the gas turbine is routed to the nearby steam turbine, which generates extra power.
