Batch Reactor Design Equations

Conversion (of substance A) is defined as  $X = \frac{\text{moles of A reacted}}{\text{moles of A fed}}$  –

This can be rephrased mathematically as  $X = \frac{N_{i0} - N_i}{N_{i0}} = 1 - \frac{C_i V}{C_{A0} V_0}$ . Then the number of moles of A in the reactor after a conversion X has been achieved is  $N_A = N_{A0} (1 - X)$ .

achieve a given conversion or determine the conversion that can be achieved in a given reactor type and size. Here we will assume that we will be given  $-r_A = f(X)$  and  $F_{A0}$ . In chapter 3 we show how to find  $-r_A = f(X)$ . Given  $-r_A$  as a function of conversion,  $-r_A = f(X)$ , one can size any type of reactor.
