Determine the short-circuit current (I_{subSC}) at the transformer's secondary terminals per its impedance. $I_{subSC} * (100\% / \%Z_{subT}) \times I_{subS} = (100/2.5) * 417 = 16,680A$. Therefore, the OCPD must be capable of safely interrupting this amount of current, along with the asymmetrical current value (usually a multiplier times the symmetrical value).

Now, we will calculate the value of the short circuit current on the secondary side of the transformer, it will help the protective device to act accordingly. $I_{sc} = ((100\%) / ((\text{Impedance of Transformer } (Z\%))) * I_{sec}$

The transformer short circuit current is calculated as follows:

$I_{\text{fault - actual}} = S_{\text{base}} \times 100 \sqrt{3} \times V_{\text{base}} \times Z\%$

where $I_{\text{fault - actual}}$ is in kA, S_{base} is in kVA, V_{base} is in V, and $Z\%$ is in percentage. This is basically a

combination of the steps in the per-unit calculation method:

~~Transformer Short Circuit Current Calculation and Solutions~~
Short-circuit calculations are performed because of several
reasons. In short-circuit studies, generally, different
characteristic values of short-circuit current e.g. peak short-
circuit current (i_p), equivalent thermal short-circuit current
(I_{th}), etc. are calculated.

A simple method for the approximation of short circuit current is the infinite bus short circuit calculation method. This method calculates the worst possible or maximum current that propagates from the transformer in case of a short circuit.

~~Short Circuit Current Calculations—Infinite Bus Method~~
The calculation of short-circuit currents in d.c. auxiliary installations, e.g., in power plants and substations is dealt with in IEC 61660-1. Contrary to the approach for the calculation of short-circuit currents in a.c. three-phase systems, the determination of the exact time course of the short-circuit current is needed besides the calculation of defined parameters [42].
